HID offers two proprietary systems

HID Prox (ca. 1991)

- ▶ 125 kHz, proprietary modulation and encoding
- ▶ No security, read-only
- ▶ Cloners readily available (Jonathan Westhues, Chris Paget); demo'd at 26C3

HID iClass (est. 2002); Subject of this talk

- ▶ 13.56 MHz, partially ISO 15693 or 14443-B
- ▶ Writeable, electronic purse function, multiple applications
- ▶ claims (3)DES security

There are many things Wiegand

The word “Wiegand” stands for one of many things:

- ▶ John R. Wiegand is a scientist who, in 1975, discovered
- ▶ the Wiegand effect which is a nonlinear magnetic phenomenon, used in specially produced
- ▶ Wiegand wire, the application of which in access control gave rise to the
- ▶ Wiegand format, which –used on keycards– indirectly defines the
- ▶ Wiegand interface and Wiegand protocol that are used between door reader and security panel.

The Wiegand interface is still widely used

- ▶ The Wiegand interface has 3 wires:
 - ▶ GND
 - ▶ DATA0
 - ▶ DATA1
- ▶ To send a '0'-bit, a pulse is sent on DATA0
- ▶ To send a '1'-bit, a pulse is sent on DATA1
- ▶ Very widely used, especially in the U.S.
- ▶ Even to this day every HID reader has a Wiegand output

The Wiegand format is a standardized ID layout

- ▶ Wiegand wire access control cards could store few bits
- ▶ The de-facto standard Wiegand format has 26 bits:

										1	1	1	1	1	1	1	1	1	1	2	2	2	2	2	2
0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5
P	Facility ID								Card ID																P
↑	even parity										odd parity														↑

Other formats provide a larger ID space

- ▶ HID takes very high pride in its support of several formats
- ▶ A **format** is the mapping between a bit string and its fields: facility ID (if any), card ID, parity bits or other checksums
- ▶ The fields need not be consecutive
- ▶ Different format lengths exist, next to the old 26-bit standard: 35 bit, 37 bit, even 44 bit

HID treats formats as a security feature

Don't succumb to the argument *made by alternate card suppliers* **that proprietary card formats are more expensive and are an attempt by manufacturers to keep you from buying cards from open sources.** *The use of proprietary formats offered by an OEM or one that is exclusive to a particular site is a desirable best practice.*

Cards with proprietary formats are much more difficult to fraudulently obtain [...]

– HID, “Best Practices in Access Control”

HID offers cards pre-programmed with a variety of formats

promises

Roads to Rome
iCLASS Security

On the air

HID Security
properties

End

- ▶ “Corporate 1000” is the HID term for custom 35-bit formats
 - ▶ The specific field mapping is unique for each format
 - ▶ HID assigns and ‘manages’ the format
 - ▶ Card orders for a format must be authorized by the ‘format owner’
- ▶ There seems to be a large and unhealthy obsession with formats

HID offers media in multiple physical und logical formats

- ▶ Physical: ISO ID-1 card, (adhesive) tag, keyfob
- ▶ Logical: 2k or 16k bits (256 or 2k bytes), 2 or 16 areas

Cards are organized in multiple logical units

- ▶ The smallest addressable unit is a **block** of 8 bytes
- ▶ Multiple blocks make up an **application area**
- ▶ There are 2 application areas per **page**
 - ▶ A 2k card has 1 page
 - ▶ A 16k card can have 1 or 8 pages
 - ▶ When 8 pages: each page has 256 bytes
- ▶ There are provisions in place for 32k credentials which have two **books** that each behave as 16k

All page layouts are similar to the 2k/2 case

Block	Content
0	Card Serial Number
1	Flags (App. Limit x , lock bits, etc.)
2	Secure Stored Value Area
3	Key 1
4	Key 2
5	Application Issuer Area
6	Application 1 (secured by Key 1)
\vdots	
x	
$x + 1$	Application 2 (secured by Key 2)
\vdots	
31	

Flags offer some freedom in credential configuration

- ▶ Variable application limit allows to customize the memory assignment for the two applications
- ▶ Lock bits allow read-only status for individual blocks 6 through 12, or all blocks
- ▶ 16 bits of One-Time Programmable (OTP) memory, can only be set from 1 to 0

Layout of block 1

Byte	Content
0	Application Limit
1	OTP
2	OTP
3	Write Lock
4	Chip Config
5	Memory Config
6	E.A.S. (unused yet?)
7	Fuses

The HID access control application is special

- ▶ First application on each credential is the HID access control application
 - ▶ Only page of 2k/2 or 16k/2 credentials
 - ▶ First page of 16k/16 credentials
 - ▶ First book of 32k credentials
- ▶ Application limit fixed to 0x12
- ▶ Secure Stored Value Area not available for purse applications
 - ▶ Pages 1–7 of 16k/16 credentials can be used for purse applications: Key 1 is the Debit key, Key 2 is the Credit key

iCLASS Security Levels

- ▶ **Standard Security:** two keys are shared across all HID readers world-wide. Swiping any standard security card in front of a standard security reader results in “beep-n-blink” of the reader. Cards are provided by HID and have a unique combination of a card ID (not UID) and a facility ID.
- ▶ **High Security:** system specific keys for each installation. As the authentication keys differ, Standard Security cards and cards from other system won't result in ‘beep-n-blink’ of the reader.
- ▶ **iCLASS Elite:** like *High Security*, but keys maintained by HID – customer gets preprogrammed cards.

Configuration Cards to switch readers to High Security

- ▶ card programmers like CP400 can create reader configuration cards
- ▶ configuration cards turn readers into high security mode by updating keys
- ▶ can optionally enable key rolling to switch all cards presented to the reader from Standard Security to the new key in High Security mode.

End

Breaking RW400 reader security

- ▶ same keys used on all Standard Security reader, incentive is high to extract keys
- ▶ break a single reader once and enter anywhere
- ▶ RW400 readers are widely available on Ebay, good choice as RW means "Read & Write" support
- ▶ RW400 – model number 6121AKN0000 attacked

In-System-Programming Connector

- ▶ same keys used on all Standard Security reader, incentive is high to extract keys
- ▶ breaking open a reader reveals **PIC18F452** CPU
- ▶ 6 pin connector on the back is a PIC In-System-Programming connector
- ▶ connector obfuscated by swapping pin 1 & 3

iCLASS Security

On the air

HID Security
properties

End

Breaking PIC18F452 Copy Protection

- ▶ created custom ICSP to delete single memory pages
- ▶ erasing boot block, flashing dumper firmware there
- ▶ erase everything except of the boot loader, putting dumper firmware on the end
- ▶ dumper firmware outputs FLASH & EEPROM content over UART
- ▶ joining binary dumps in a single hex file – flashing readers with In-System-Debug enabled

Key Spotting - Finding the (3)DES Encryption Keys

- ▶ easy to spot in the 256 byte EEPROM dump
- ▶ four 8 byte blocks look random in the dump
- ▶ using In-System-Programmer, narrowing down keys by changing bytes
- ▶ changes in the DES authentication key will stop “beep-n-blink”
- ▶ changes in the 3DES encryption key will result in garbled Wiegand packets
- ▶ stored keys need to be reverse-permuted to make them usable in a standard OMNIKEY reader

```

Authenticators seem to be 4 bytes

- ▶ Mutual authentication:
 - ▶ No random number from card, but stored value block is part of authentication
 - ▶ 4 byte random number from reader
 - ▶ 4 byte authenticator from reader
 - ▶ 4 byte authenticator from card
- ▶ Write authentication:
 - ▶ 4 byte authenticator
 - ▶ Strange behaviour for special blocks:
 - ▶ Writing key means transmitting XOR of current and desired value
 - ▶ Writing to stored value block swaps low and high word
- ▶ No message authentication!
 - ▶ CRC are similar to ISO 15693 but with custom post XOR

All the king's horses and all the king's men

- ▶ Authentication key derivation based on CSN, no binding between CSN and anything else
- ▶ Verbatim copy of blocks is possible
 - ▶ Content encryption does not help against impersonation
- ▶ No MAC: Man in the middle attacks lead to privilege escalation
 - ▶ Use an authorized card to survive the mutual authentication, then do whatever you want
- ▶ Standard Security is broken, on the order of Legic Prime or HID Prox
