

Legic Prime: Obscurity in Depth

Henryk Plötz, Karsten Nohl

ploetz@informatik.hu-berlin.de,
nohl@virginia.edu

December 28th 2009

Legic tokens are RFID access and payment cards

- ▶ Contactless smart cards at 13.56MHz
 - ▶ Legic Prime: Proprietary, marketed since 1992
 - ▶ Legic Advant: ISO compliant, marketed since 2004
- ▶ Predominantly used in access control, but payment applications exist (i.e., cafeteria)
- ▶ Can hold several applications, but this feature is rarely seen

Attack overview

Analyzing LEGIC
RF

The case of the CRC

The obfuscation
function

Understanding the
Legic Prime
protocol

Mastering MTSC

Comprehending
card contents

Conclusions

Legic Prime

- ▶ Old card type, as old as Mifare Classic (and at least as insecure)
- ▶ Proprietary radio protocol (applied to become ISO 14443 Appendix F): „LEGIC RF“
- ▶ Proprietary ‚Legic Encryption‘
- ▶ Slow data rate (~ 10 kbit/s), comparatively high read range (supposedly up to 70 cm)
- ▶ Card types: MIM22 (outdated), MIM256 (234 bytes storage), MIM1024 (1002 bytes storage)

Attack overview

Analyzing LEGIC
RF

The case of the CRC

The obfuscation
function

Understanding the
Legic Prime
protocol

Mastering MTSC

Comprehending
card contents

Conclusions

Legic Advant

- ▶ New card type, developed in the 2000's
- ▶ Based on ISO 14443A or ISO 15693
- ▶ 3DES or AES, also backward compatible to 'Legic Encryption'
- ▶ Several ATC card types with varying sizes (15693: 128-944 bytes, 14443: 544-3680 bytes)
- ▶ Not yet analyzed by us, therefore not covered in this talk

Analyzing LEGIC
RF

The case of the CRC

The obfuscation
function

Understanding the
Legic Prime
protocol

Mastering MTSC

Comprehending
card contents

Conclusions

- ▶ Shrouded in a cloud of closed-ness and exclusivity
- ▶ Compared to Mifare: much harder to get cards and readers on the free market (this is on purpose)
- ▶ No documentation available beyond layer 1+2 (in rejected ISO 14443F)
- ▶ Most marketed feature and main difference to other systems: Master Token System Control

Master Token System Control

Mastering MTSC

Comprehending
card contents

Conclusions

The powerful LEGIC Master-Token System Control (MTSC) [...] is unique in the security industry. With MTSC no sensitive passwords are needed. Instead, a special physical Master-Token [...] is used containing a unique genetic code which securely links cards and readers. – Source:

http://www.legic.com/unique_security.html

- ▶ Cards are segmented and access is regulated on a per-segment basis
- ▶ Segment access is bestowed not through the knowledge of keys or passwords but through a physical token
- ▶ The MSTC token itself is a Legic card (either Prime or Advant)

Segment protection

- ▶ Node identifier in the master token structure is called the stamp (or ‚genetic code‘)
- ▶ Segments on cards are imprinted with a stamp on creation
 - ▶ Stamp comes from the token that authorized the creation
 - ▶ Stamp can not be changed
- ▶ Optionally, segments can be „read protected“
- ▶ Readers are initialized with access rights for none/one/multiple stamps
- ▶ Card–Reader interaction:
 - ▶ Read read-protected segment and write: only if reader has access rights for that segment's stamp
 - ▶ Read non-read-protected segments: All readers can do this

Legic Prime:

Legic Prime
protocol

Mastering MTSC

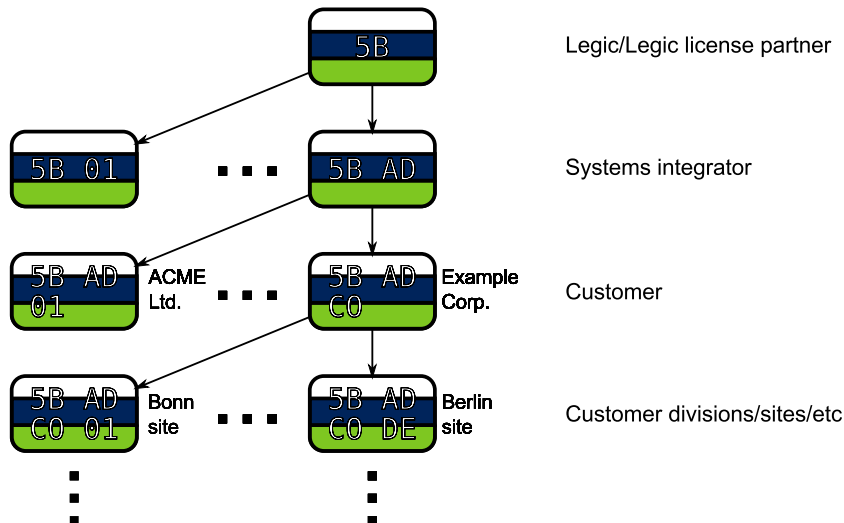

Comprehending
card contents

Conclusions

MTSC Structure

- Token structure is hierarchical: a token can only create objects with higher nesting level than its own → longer stamp, but same prefix

Conclusions

Token Types

General Authorization Media (GAM)

Token-creating token that carries the temporary authorization to create sub-tokens

Identification Authorization Media (IAM)

Segment-creating token that carries the temporary authorization to create segments on cards

System Authorization Media (SAM)

'Reader-creating' token that bestows the permanent authorization to write to existing segments on cards (and read read-protected segments)

Conclusions

Token Sub-Types

- ▶ For the SAM (a.k.a. SAM63, a.k.a. ‚Taufkarte‘), which ‚launches‘ readers (‚taufen‘), there is a counterpart: SAM64 (a.k.a. ‚Enttaufkarte‘) to de-launch readers (‚enttaufen‘)
- ▶ Other types (possibly restricted to advant):
 - XAM** Permanent permission to create segments (e.g. a launching version of IAM)
 - IAM+** Restricted version of IAM, which only allows to create a given number of segments
- ▶ There are references to SAM4 ‚Parametrierkarte‘, which changes reader parameters. Also some systems may use other ‚SAM...‘ types for sneakernet purposes.

function

Understanding the
Legic Prime
protocol

Mastering MTSC

Comprehending
card contents

Conclusions

- ▶ ISO 14443 Annex F gives general parameters:
 - ▶ RWD to TAG: Pulse-pause modulation, 100% AM, off-duration: $20\mu\text{s}$, ,0'-bit: on-duration $40\mu\text{s}$, ,1'-bit: on-duration $80\mu\text{s}$, data rate 10 kHz–16.6... kHz (data-dependent)
 - ▶ TAG to RWD: On-off-keying, load-modulation, subcarrier $f_c/64$ ($\sim 212\text{kHz}$), bit-duration: $100\mu\text{s}$
 - ▶ Framing „defined by the synchronization of the communication“
 - ▶ No frame start/stop information for tag originated frames

Sniffing LEGIC RF

- ▶ Sniffing with OpenPICC2 (fixed threshold, not so good) or Proxmark3 (hysteresis, much better) and oscilloscope or logic analyzer

protocol

Mastering MTSC

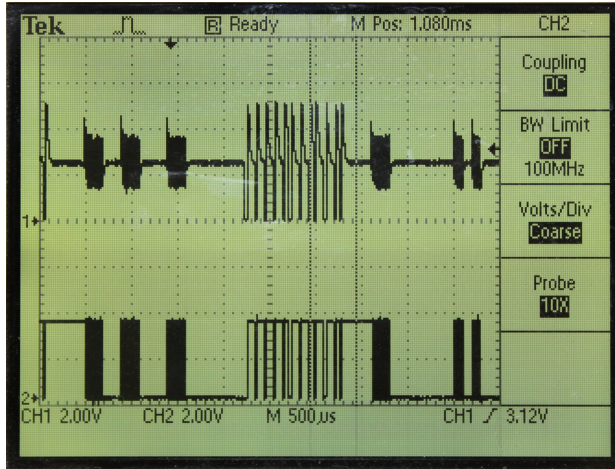

Comprehending
card contents

Conclusions

Decoding

- ▶ Custom decoder in C
- ▶ Delay between RWD command and TAG response seems to be constant, approx $330\mu\text{s}$
- ▶ As expected: TAG-originated frames are not delimited, length unclear

- ▶ Comparing many traces yields the protocol structure:
 - ▶ Setup, once per session:
 - ▶ 7 bits from RWD
 - ▶ 6 bits from TAG
 - ▶ 6 bits from RWD
 - ▶ Repeat several times, once for each byte requested:
 - ▶ 9 bits from RWD (depending on card type: 11 bits for MIM1024)
 - ▶ 12 bits from TAG

Comprehending
card contents

Conclusions

Assumption of Encryption

- ▶ Let the 7–6–6 exchange be the ‚setup phase‘ and the remainder of the session be the ‚main phase‘
- ▶ First 7-bit-command from RWD is more or less random, but always has first bit set, name it RAND. Assumption: IV of a stream cipher.
 - ▶ RNG is weak: a) Too small; b) 0x55 in ~10% percent of cases (vs. expected 1.5%)
- ▶ For a given RAND the rest of the setup phase is identical over all cards of the same type (MIM256 and MIM1024 differ by one bit).
- ▶ Within a card type, for a fixed RAND, all reader command sequences are identical.

→ Looks like a stream cipher with weak IV from reader and no random from the card

„Get UID“ command sequence

- ▶ Each reader-card request-response pair only transmits one byte of payload
- ▶ The UID is transmitted in order first byte, fourth/last byte, third byte, second byte (compared to the display in the GUI)
- ▶ Each response is protected by a 4 bit CRC
- ▶ A fifth byte is transmitted after the UID, this is an 8 bit CRC over the UID, stored on the card itself

Comprehending
card contents

Conclusions

Read commands

- ▶ Hypothesis: Command is 1 bit command code, 8 bit (or 10 bit) address, response is 8 bit data and 4 bit CRC
- ▶ „Get UID“ isn't really requesting the UID, but simply reading the first 5 bytes of memory
- ▶ Hypothesis confirmed: Lowest bit (first bit transmitted) of command is command code, must not be changed; remaining 8 bits are address

Conclusions

Read commands (cont.)

- First command of „Get UID“ sequence is really „Read Byte 0“

Cmd	Arg								
C	x	x	x	x	x	x	x	x	Original („Read Byte 0“)
C	\bar{x}	x	x	x	x	x	x	x	New: „Read Byte 1“
C	x	\bar{x}	x	x	x	x	x	x	New: „Read Byte 2“
C	\bar{x}	\bar{x}	x	x	x	x	x	x	New: „Read Byte 3“
etc. pp.									

- Timing is important. Also: Only one command per setup phase → **4 s** to read a full MIM256 card

Read commands (cont.)

- First command of „Get UID“ sequence is really „Read Byte 0“

Cmd Arg

C x x x x x x x x Original („Read Byte 0“)

C \bar{x} x x x x x x x New: „Read Byte 1“

C x \bar{x} x x x x x x New: „Read Byte 2“

C \bar{x} \bar{x} x x x x x x New: „Read Byte 3“

etc. pp.

- Timing is important. Also: Only one command per setup phase → **4 s** to read a full MIM256 card

ACHIEVEMENT UNLOCKED:

Access All Areas

You can now read all segments, even read protected ones

Attacking the CRC

- ▶ CRC in stream cipher is well known to be malleable (WEP, Mifare Classic, ...)
- ▶ With unknown CRC function, a simple approach is to brute-force the difference values for all 1-bit changes. The differences are fully additive

Data								CRC				
x	x	x	x	x	x	x	x	x	x	x	x	Original (valid)
\bar{x}	x	x	x	x	x	x	x	x	x	\bar{x}	x	Try (invalid)

Note: These examples are synthetic and do not use the actual CRC polynomial

Conclusions

Experimentally determine obfuscation stream

- Vary first bit of command at each time offset → gives first bit of obfuscation stream at that time offset

Note: These examples are synthetic and do not use the actual obfuscation stream

- Interpretation: The obfuscation stream generator generates a new bit approx. every $100\ \mu\text{s}$ (more like $99.1\ \mu\text{s}$, might be reader-specific)

Complete break, even without a microscope: Generate arbitrary amounts of obfuscation stream by leveraging a few bits of known plaintext (optimized attack: 14 hours preparation, 4 kilobytes storage; naive attack: 4 days preparation, 80 kilobytes storage)

Conclusions

CRC revisited

- ▶ A CRC is determined by four parameters: register width, polynomial, initial value, final XOR
- ▶ Storage CRC is 8 bits, transport CRC is 4 bits: Easy to brute-force over the full parameter space
- ▶ If all the known inputs are of the same length, initial value and final XOR are equivalent: Fixing one to an arbitrary value gives a solution for the other
- ▶ Better than brute force: Analysis of the 1-bit differences allows direct determination of the CRC parameters

Conclusions

Sniffing a master token load

- ▶ Analysis of a „load IAM“ or „launch reader“ process reveals:
 - ▶ UID is read, UID-CRC is read
 - ▶ Bytes 6 and 5 are read (in that order)
 - ▶ Byte 7...(7+stamp length) are read
 - ▶ Byte 21 is read
- ▶ Launch process takes a long time, ~ 15 s, providing the illusion that something profound is happening (key-derivation? lengthy EEPROM reprogramming?)
 - ▶ On the radio channel, byte 4 (UID-CRC) is read every 1 s, to ping whether the card is still there

Conclusions

CRC, again

- ▶ Analysis of CRC bit differences reveals: same CRC polynomial as for the UID
- ▶ Further analyses find a common set of parameters for the UID CRC and the master token CRC
 - ▶ Disambiguates initial value/final XOR
 - ▶ Master token CRC is calculated over:
 1. UID, bytes 0 thru 3
 2. Bytes 6 and 5
 3. Byte 7
 4. Stamp, bytes 8 thru $(8 + (\text{stamp length}) - 1)$
- ▶ Can now emulate IAM and SAM for arbitrary stamps of length 4

Comprehending card contents

- ▶ Reverse engineering card contents not necessary for the standardized types (e.g. cash, access, biometric): Simply use the regular software together with the Uber-IAM
- ▶ Otherwise, if available, use csg files (legic segment definition) to aid in interpretation
- ▶ Data on the card is further obfuscated: All payload bytes are XORed with some value.

That value is the CRC of the UID (which is also stored on the card)

Conclusions

Card format

- ▶ 4 bytes UID + 1 byte CRC
- ▶ 2 bytes decremental field (DCF), is 0x60 0xea for all cards that aren't master token
- ▶ 6 bytes unknown/unused/fixed, might be a version identification, possibly related to old unsegmented cards
- ▶ 6 bytes segment header backup area + 1 byte CRC
- ▶ 2 bytes unknown/unused
- ▶ remainder: obfuscated payload

Conclusions

Segment format

- ▶ Segment header is 4 bytes + 1 byte CRC
 - ▶ 1st byte: lower byte of segment length (including header)
 - ▶ 2nd byte, lower nibble: high nibble of segment length
 - ▶ 2nd byte, high nibble: flags: 0x8 == last segment flag, 0x4 == segment valid flag (if flag is not set, the segment is deleted)
 - ▶ 3rd byte: WRP, length of write protected area of the segment. Always includes the stamp length
 - ▶ 4th byte, bits 4 thru 6: WRC
 - ▶ 4th byte, MSBit: RD, read protection
- ▶ Segment header write procedure:
 - ▶ Save old segment header to backup area
 - ▶ First byte of backup area := 0x80 (,dirty') | segment number
 - ▶ Write new segment header
 - ▶ Clear dirty flag in backup area

Conclusions

Root Security Issues

- ▶ No keys, (no key management, no card authentication, no reader authentication)
 - Spoofing, skimming
 - Segments can be created out of thin air
 - Master token can be created out of thin air
- ▶ No authorisation necessary for master token use, master token not inherently necessary for segment creation
 - Master token clonable

Conclusions

Proxmark3 allows pen-testing Legic systems

- ▶ We release today: Legic Prime reader emulation
 - ▶ Test whether an access cards is Legic Prime (or HID, Mifare Classic) and hence vulnerable
 - ▶ Test whether private data is stored on the card (including in read-protected segments)
- ▶ **Proxmarks are available at 26C3**; look for the green laser in the basement

- ▶ We do not release: Card emulation, full protocol
 - ▶ Reverse-engineering these components is not hard
 - ▶ Therefore: Upgrade ASAP.

Conclusions

Please upgrade, just not to HID!

- ▶ Several RFID cards have been publicly broken over the past years: Mifare Classic, NXP Hitag2, Legic Prime
- ▶ Meanwhile, **HID Prox** – the card with the least security – still has a reputation of being secure
- ▶ Let us recap:
 - ▶ HID Prox cards can be read and emulated with a \$20 device (c.f. proxpick.com)
 - ▶ Reading distance is at least 20cm
 - ▶ No crypto, no obfuscation, no protection; but: good lawyers

Conclusions

Conclusions and Outlook

- ▶ Even multi-level obfuscation does not prevent reverse-engineering
- ▶ Access cards at the very least need inherent protection in form of good crypto and secret keys
- ▶ Legic Prime analyzed head to toe
 - ▶ No actual, inherent security found
 - ▶ Advertised range ~70 cm & card completely unprotected against skimming → more significant break than with Mifare Classic
- ▶ Once again: Security by obscurity does not work
